Push the limits of Golden Gate Assembly

Golden Gate Assembly (1,2) allows for the efficient and seamless assembly of DNA fragments using activities of Type IIS restriction enzymes and T4 DNA Ligase. With constant advances in both the development of new enzymes and research on maximizing enzyme functionality (e.g., higher fidelity) NHE is the industry leader in pushing the limits of Golden Gate Assembly and related methods.

Advantages:

- Clone seamlessly with no scars remaining after assembly
- Perform single insert cloning in just 5 minutes using one reaction
- Construct libraries with high efficiency
- Assemble multiple fragments (2-3+) in one go, in a single reaction
- Experience high efficiency even with regions of high GC content and areas of repeats
- Use with a broad range of fragments sizes (~100 bp to 15 kb)

Expanded products Type IIS Restriction Enzymes used in Golden Gate Assembly

Type IIS restriction enzymes recognize asymmetric DNA sequences and cleave outside of their recognition sequence. Type IIS enzymes commonly used in Golden Gate Assembly are listed below. NHE assembly often uses 63 Type IIS restriction enzymes. Please visit www.nhe.com for comprehensive data.

What users are saying

"I've been using NHE Golden Gate Assembly for a while now and I'm really impressed with the results. The efficiency is high and the process is so easy to follow. I've been able to assemble large constructs with ease. The NHE team is also very responsive to customer inquiries. I highly recommend NHE Golden Gate Assembly to anyone looking for a reliable and efficient cloning method." - Dr. John Doe, University of California, Berkeley

GOLDEN GATE ASSEMBLY'S WORKFLOW

NHE® Golden Gate Assembly Kits (BsmBI-v2 or BstI-HI-v2)

The ability to insert DNA into a sequence depends on the choice of which Type IIS restriction enzyme to use. The NHE Golden Gate Assembly Kits (BsmBI-v2 or BstI-HI-v2) are designed to provide the highest efficiency and most reliable results. The kits include all the necessary components for successful assembly, including the enzymes, ligase, and buffers. The kits are also compatible with a wide range of DNA fragments and vectors.

COMPARING GOLDEN GATE ASSEMBLY WITH OTHER METHODS

Visit www.nhe.com for more information on NHE Golden Gate Assembly and related products. The NHE team is always happy to assist with any questions or inquiries.

Advances in Ligase Fidelity

Research at NHE has led to an improved understanding of ligase fidelity. This has resulted in the development of new ligase enzymes with enhanced fidelity. The new enzymes are designed to minimize errors during the ligation process, resulting in higher fidelity assemblies. This is particularly important for applications requiring high accuracy, such as the construction of libraries or the assembly of large constructs.

Visit www.nhe.com/GoldenGate to learn more and view related videos.

Expanded "Assembly" standard for MoClo, GoldenBraid 2.0, and Other Modular Golden Gate Assembly Methods

MoClo (and GoldenBraid 2.0) uses 1 level of restriction activity. The standard assembly process for MoClo involves the use of a single restriction enzyme to create a specific assembly site. This standard process is now being expanded to include other modular Golden Gate Assembly methods, such as GoldenBraid 2.0. The expanded standard will allow for the seamless integration of different modular components, resulting in more complex and versatile assemblies.

Expanded restriction site compatibility

- Level 0 (Basic) (no restriction sites)
- Level 1 (Restriction sites)
- Level 2 (Restriction sites + 5' and 3' overhangs)

Quote from Zeng *et al.*, 2016

- From Materials and Methods, Virus and cells section
“All experiments using live virus was conducted under biosafety level 2 (BSL2) conditions.”

From the first paragraph of the Discussion

“In this study, we have developed a fast and cost-effective method for reverse genetics of coronaviruses by combining two approaches developed by others (29, 30). Our method allows the genomes of coronaviruses to be split into multiple fragments and inserted into a BAC plasmid with a single step. Recombinant viruses can then be efficiently rescued by direct transfection of the BAC construct. As the genomes can be divided into multiple short fragments, mutations can be introduced into individual fragments easily (31). Using this method, we successfully rescued three recombinant viruses derived from SL-CoV WIV1 (rWIV1, rWIV1-DX, and rWIV1-GFP-DX).”

WIV SARS-CoV Reverse Genetics System

FIG. 1 Strategy for construction of an infectious WIV1 BAC clone. (A) Genomic structure of WIV1. (B) The mutations are indicated under the stars. C1575A was used to ablate a natural BglII site at nucleotide 1571 (▼), and T27527C was used to disrupt a potential T7 stop site. The others were for introducing BglII sites (▼). (C) The WIV1 genome was split into eight contiguous cDNAs (A to G); A, nt 1 to 4387; B, nt 4388 to 8032; C1, nt 8033 to 10561; C2, nt 10562 to 12079; D, nt 12080 to 17017; E, nt 17018 to 22468; F, nt 22469 to 27352; G, nt 27353 to 30309. Unique BglII sites were introduced into the fragments by synonymous mutations to make these fragments capable of unidirectional ligation along with native BglII sites in the genome. The original nucleotides are shown above the flanking sequences of corresponding fragments. A poly(A) sequence was added to the 3' terminus of fragment G. A CMV promoter, HDV ribozyme, and BCIH transcriptional terminal signal were inserted into pBeloBAC11 between BamHI and HindIII sites. SacII and AseI sites were introduced between the CMV promoter and ribozyme. Fragments A to G were inserted into the pBAC-CMV plasmid in a single step.

SARS-CoV-2 SimPLOT

- "A recent study found that a human ACE2-binding ridge in SARS-CoV-2 RBD takes a more compact conformation compared with the SARS-CoV RBD; moreover, several residue changes in SARS-CoV-2 RBD may also enhance its human ACE2-binding affinity [13]. The core residues in RBM which may related to higher human ACE2-binding affinity than SARS-CoV are 100% identical between SARS-CoV-2 and CoV-Pangolin-2020. Therefore, pangolin-CoV-2020 (CoV-pangolin/GD) potentially recognizes human ACE2 better than the SARS-CoV."

Received 20 May 2007/Accepted 15 November 2007

Severe acute respiratory syndrome (SARS) is caused by the SARS-associated coronavirus (SARS-CoV), which uses angiotensin-converting enzyme 2 (ACE2) as its receptor for cell entry. A group of SARS-like CoVs (SL-CoVs) has been identified in horseshoe bats. SL-CoVs and SARS-CoVs share identical genome organizations and high sequence identities, with the main exception of the N terminus of the spike protein (S), known to be responsible for receptor binding in CoVs. In this study, we investigated the receptor usage of the SL-CoV S by combining a human immunodeficiency virus-based pseudovirus system with cell lines expressing the ACE2 molecules of human, civet, or horseshoe bat. In addition to full-length S of SL-CoV and SARS-CoV, a series of S chimeras was constructed by inserting different sequences of the SARS-CoV S into the SL-CoV S backbone. Several important observations were made from this study. First, the SL-CoV S was unable to use any of the three ACE2 molecules as its receptor. Second, the SARS-CoV S failed to enter cells expressing the bat ACE2. Third, the chimeric S covering the previously defined receptor-binding domain gained its ability to enter cells via human ACE2, albeit with different efficiencies for different constructs. Fourth, a minimal insert region (amino acids 310 to 518) was found to be sufficient to convert the SL-CoV S from non-ACE2 binding to human ACE2 binding, indicating that the SL-CoV S is largely compatible with SARS-CoV S protein both in structure and in function. The significance of these findings in relation to virus origin, virus recombination, and host switching is discussed.

RmYN02 - A Red Herring?

- Zhou et al., 2020 publish paper describing Bat CoV rmYN02. Next generation sequencing was done on pooled bat samples to develop two genome sequences – RmYN01 and RmYN02. Claim that RmYN02 contains inserted nucleotides at the S1/S2 cleavage site. Assert that the SARS-CoV-2 FCS is therefore of natural origin. No virus is available for peer confirmation.

HIV Sequences in the SARS-Cov-2 Spike Gene

Adapted from Perez, 2020

~~SECRET//NOFORN~~

~~SECRET//NOFORN~~

Perez, 2020 Scientific Challenges

- None of the six proposed regions are identical at either the nucleotide or amino acid level with the corresponding HIV/SIV segments. None of the six peptides are related to identified immunosuppressive regions of HIV and SIV (Retroviral ISU Domains). The HIV gp41 immunosuppressive (ISU) Domains sequence is KQLQARILAVERYLKDDQLLGG - this sequence does not match any of the six. Four of the six regions either perfectly or almost perfectly match corresponding peptides in multiple Pangolin CoVs - Perez did not account for Pangolin genomes in the paper. Several are only found in Pangolin CoV Spike sequences and not in Bat CoV Spike sequences, indicating that the SARS-CoV-2 Spike NTD region originated from a Pangolin CoV template.

Alternative Scenario

~~SECRET//NOFORN~~

~~SECRET//NOFORN~~

Hypothetical Laboratory Origin of SARS-CoV-2

- WIV conducted a longitudinal studies to isolate a large number of bat Coronaviruses from multiple locations in China (2011-2015) WIV Developed Reverse Genetic System, assembled WIV1 full-length infectious clone, and created chimeric viruses exchanging the WIV1 spike gene with the spike gene from other bat Coronaviruses (2015-2017) WIV and other Chinese scientists conduct gain of function studies on SARS, MERS, IBV, and PEDV to insert furin cleavage sites demonstrating increased virulence of the chimeric viruses WIV conducted in vivo and in vitro studies to characterize the bank of bat Coronaviruses WIV conducted the live bat Coronavirus studies under BSL2 conditions Chinese BSL2 and US BSL2 conditions are different Chinese labs have had a history of virus escapes from BSL2 laboratories Hypothesis: Between 2017 and 2019, WIV created a full-length infectious clone in pBAC-CMV using an unpublished bat Coronavirus genome as template (BatCoVX) Hypothesis: Between 2017 and 2019, WIV created chimeric Bat-CoV-X viruses using the pBAC-CMV-BCoVX backbone and swapping out key cassettes with other bat Coronaviruses (RBD, RBM, etc.) and adding additional features such as a furin cleavage site Hypothesis: In 2018-2019, WIV conducted in vitro and in vivo studies to characterize the BatCoVX chimeric viruses under BSL2 conditions Hypothesis: In mid-2019, one of the not fully characterized Bat-CoV-X chimeric viruses escaped from the WIV facilities and begins infecting civilians in the city of Wuhan Hypothesis: Starting in mid-2019 through present, WIV and other Chinese laboratories conduct studies to characterize the Chimeric BCoVX virus that escaped (now called SARS-CoV-2) WIV (Zhou et al., 2020) publishes the 2019-nCoV genome sequence showing relatedness to RaTG13 (a previously unpublished genome) BatCoVX likely highly related to RaTG13 Hypothesis: Beginning in early 2020, WIV and other government controlled agencies begin to publish obfuscation information to drive the narrative that SARS-CoV-2 is of natural origin and resulted from natural recombination RaTG13 RMYN02 Pangolin CoV's

~~SECRET//NOFORN~~

Concluding Points

- WIV possesses a bank of Bat Coronavirus isolates. WIV has scientists experienced in Coronaviriology and Coronavirus infectious clone generation. WIV scientists generated chimeric SARS-CoV and Bat-CoV spike genes to identify minimal Spike Receptor Binding Domain cassette that could transfer receptor binding specificity (Ren et al., 2008). WIV possesses an existing and published Coronavirus Reverse Genetics System (Zeng et al., 2016) utilizing their pBAC-CMV plasmid. WIV has utilized the pBAC-CMV-WIV1 Full-length clone to generate chimeras with Bat-CoV spike genes (Hu et al., 2017). WIV has BSL2/BSL3/BSL4 animal facilities. WIV has multiple in vitro assays (apoptosis, IFN- β induction, etc.) to characterize their Bat Coronavirus and chimeric Bat Coronavirus. WIV and other Chinese researchers have conducted Gain of Function studies in SARS, MERS, IBV, and PEDV to add Furin Cleavage Sites to CoV Spike protein. The absence of a published progenitor virus for SARS-CoV-2 only indicates that it has not been published, not that it does not exist. The genomic sequence of SARS-CoV-2 has Type II restriction sites that are consistent with being generated by the Golden Gate Cloning system utilizing the published pBAC-CMV plasmid. The SARS-CoV-2 genome has several break points where homology jumps from Bat Coronavirus to Pangolin Coronavirus, which is consistent with a synthesized chimeric virus. The SARS-CoV-2 Spike protein similarity with RaTG13 and Pangolin CoV Spike proteins may also be explained by use of cassettes swapped into the base virus – these break points align with those identified by WIV scientists (Ren et al., 2008). The Pangolin RBD cassette is 100% identical at the amino acid level while the DNA sequence appears to be codon optimized. There are no other published SARS lineage Betacoronaviruses that possess a Furin Cleavage Site in their Spike protein (RmYN02 does not have an insertion) and the SARS-CoV-2 FCS does not appear to be inserted via the same mechanism that drives Influenza virus insertions of polybasic cleavage sites. Zeng et al., 2016 stated that “All experiments using live virus was conducted under biosafety level 2 (BSL2) conditions” which would make an accidental release of a pathogenic Bat-CoV capable of binding human ACE2 more likely. A chimeric virus comprised of segments from natural Bat-CoV genomes would appear like a recombinant virus.

The molecular biology capabilities of WIV and the genome assessment are consistent with the hypothesis that SARS-CoV-2 was a lab-engineered virus that was part of a bank of chimeric viruses in Zhen-Li Shi's laboratory at WIV that escaped from containment.
